

# **Lesson 10: Urban Network Analysis with GIS**

**Dr. Kam Tin Seong  
Assoc. Professor of Information Systems**

**School of Computing and Information Systems,  
Singapore Management University**

**2019-01-01 (updated: 2021-10-24)**

# Content

- Why analyse with network?
- Network model
- Real world network system
- Complexity of urban road network
- Shortest path analysis algorithm
- Network analysis methods

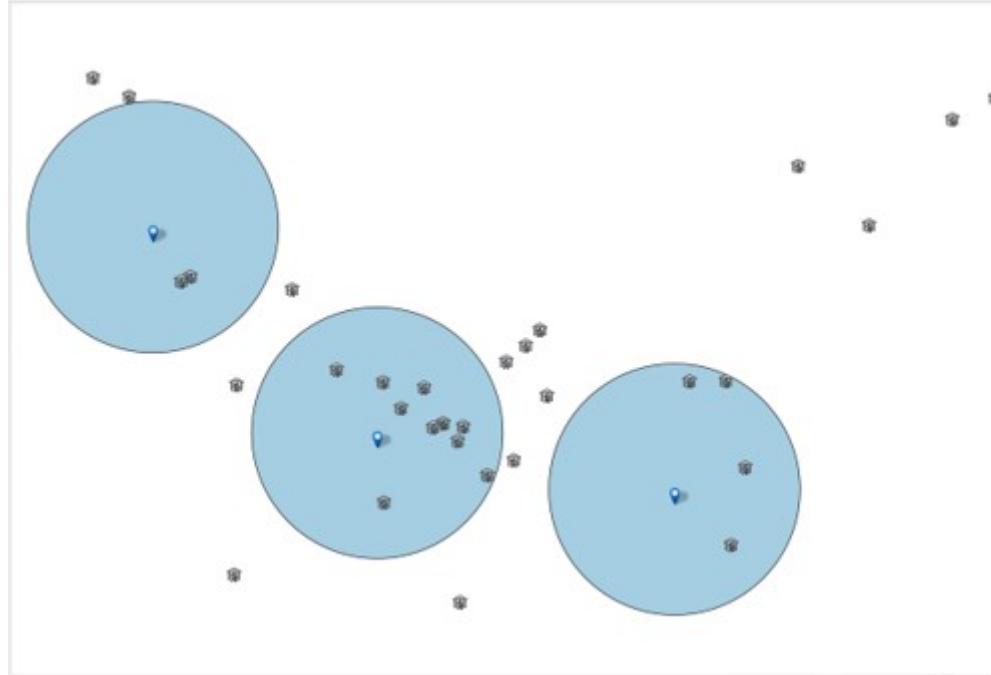

# Location question

- How to assign the eldercare centres to the closest polyclinic?

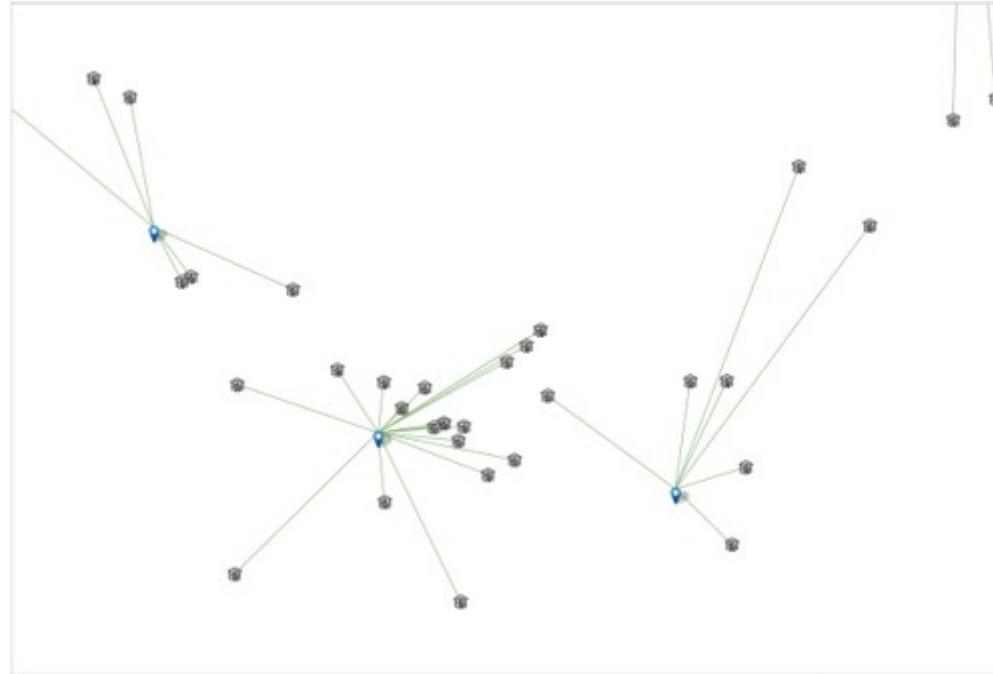

# GIS answer

- Using buffer analysis

# GIS answer

- Using desire line analysis (mmqgis plugin is needed).

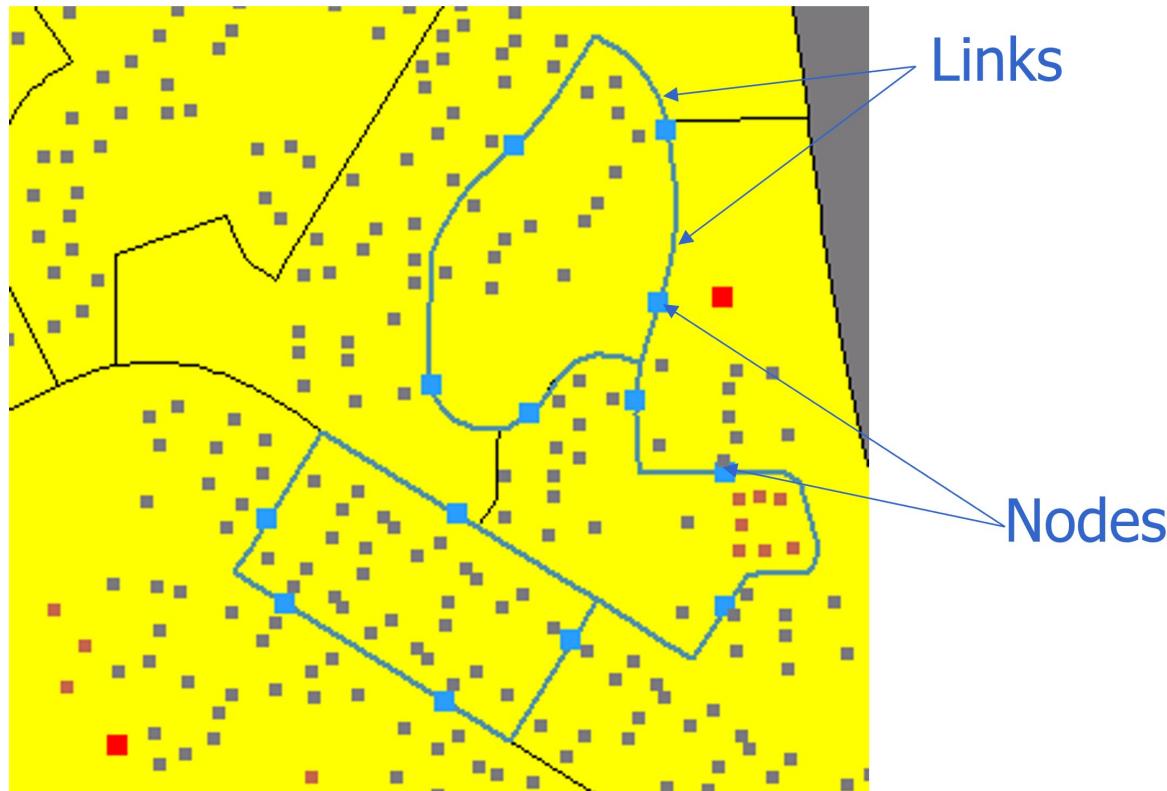

# Limitation of the GIS answers

- Failed to consider the actual road network.

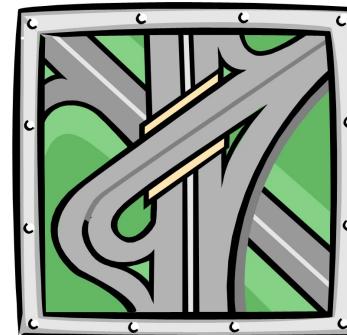

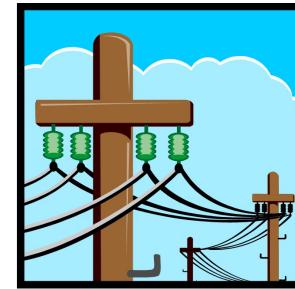

# A Network Model

- A **link** refers to a linear segment defined by two end points. Also called **edges**.
- A **node** refers to an end point of a link.

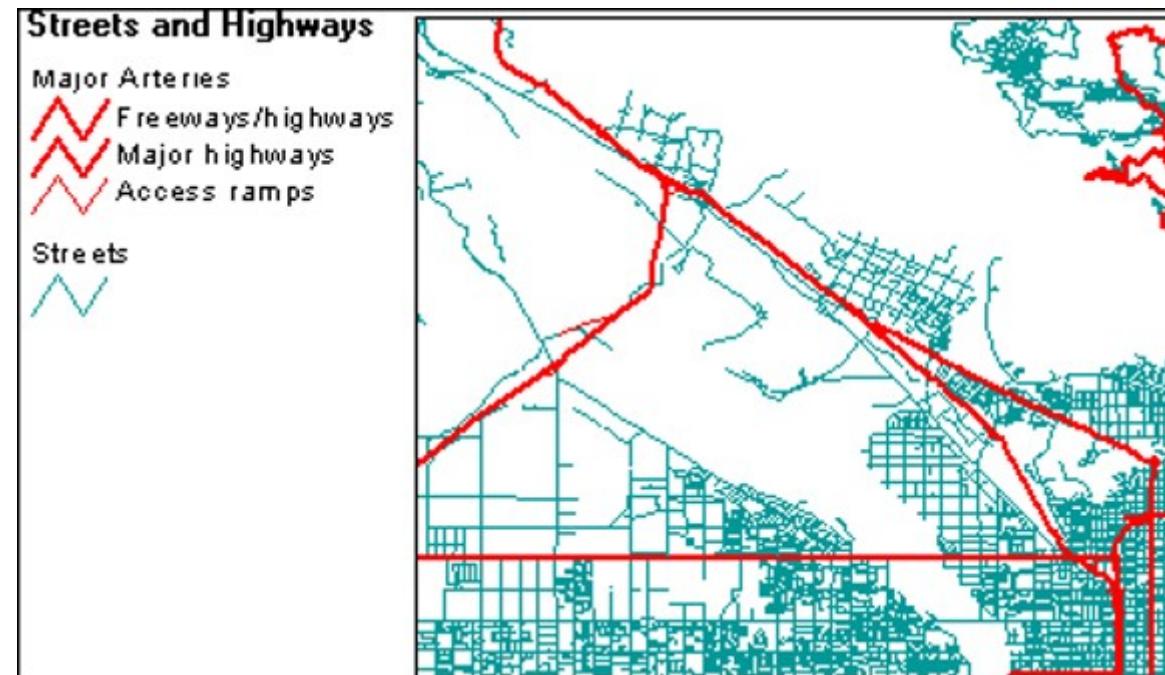

# Two types of networks

- Geometric
  - Directed flow, away from sources and toward sinks
  - Resources make no travel decisions
- Topologic
  - Undirected flow
  - Resources make their own travel decisions

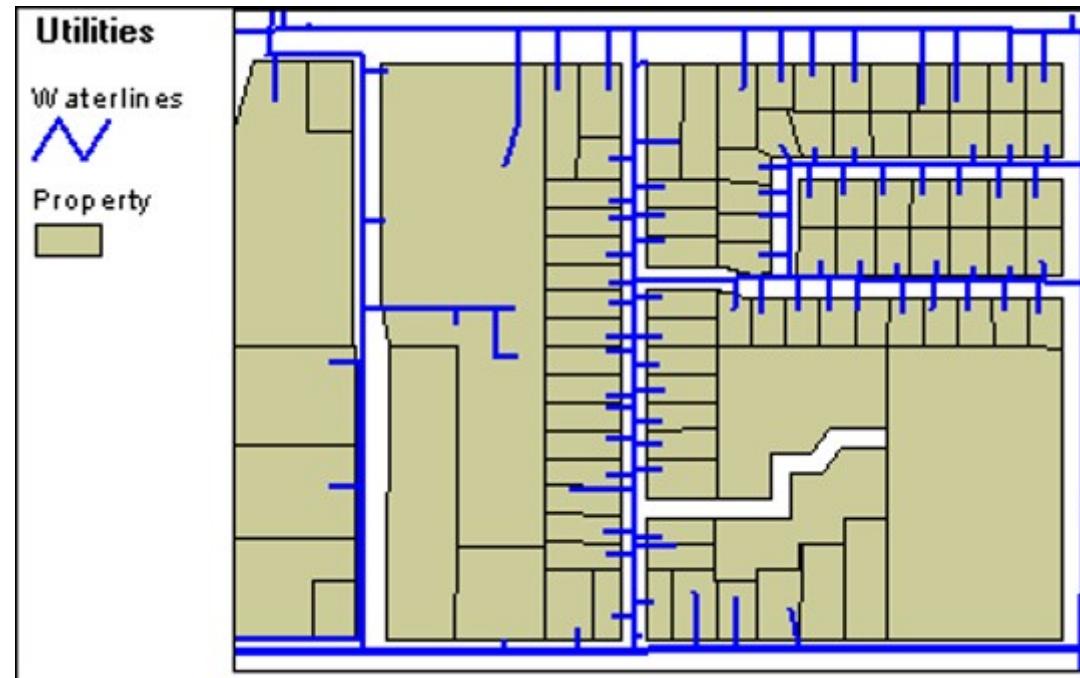

# A Transportation Network

This network theme represents city streets and highways. Several theme attributes, such as speed limits, the number of lanes a street has, or which streets are one-way or two-way, can affect the flow of goods and services through a network.

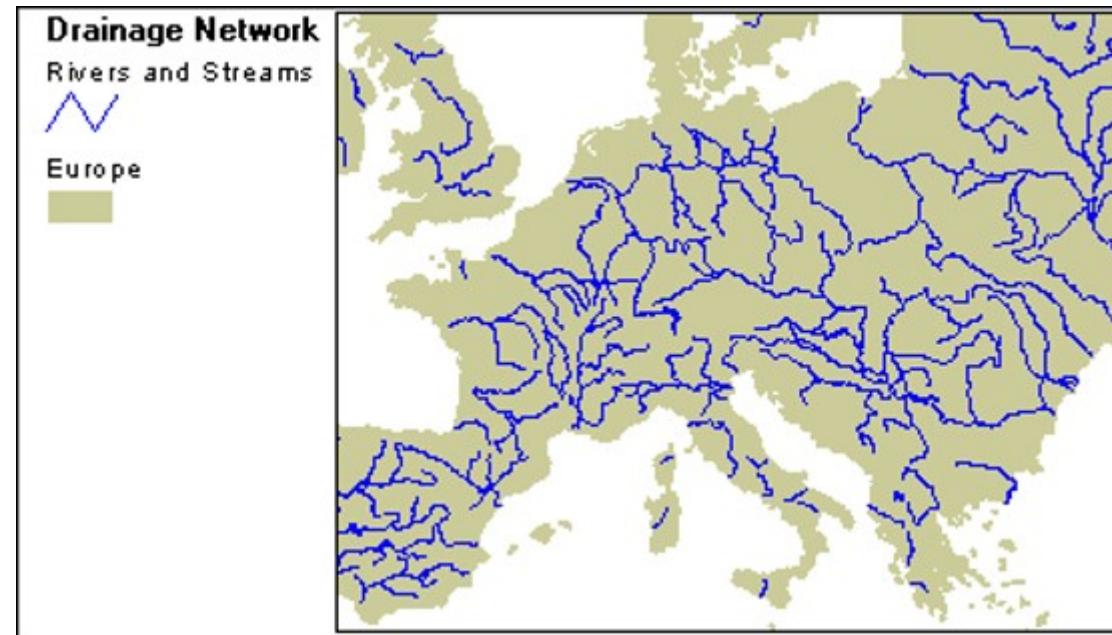

# An Utility Network

Utilities can also be network themes. In this example, the diameter of the waterlines, the system's water pressure, and the location of control valves can affect the flow of the water through the network.

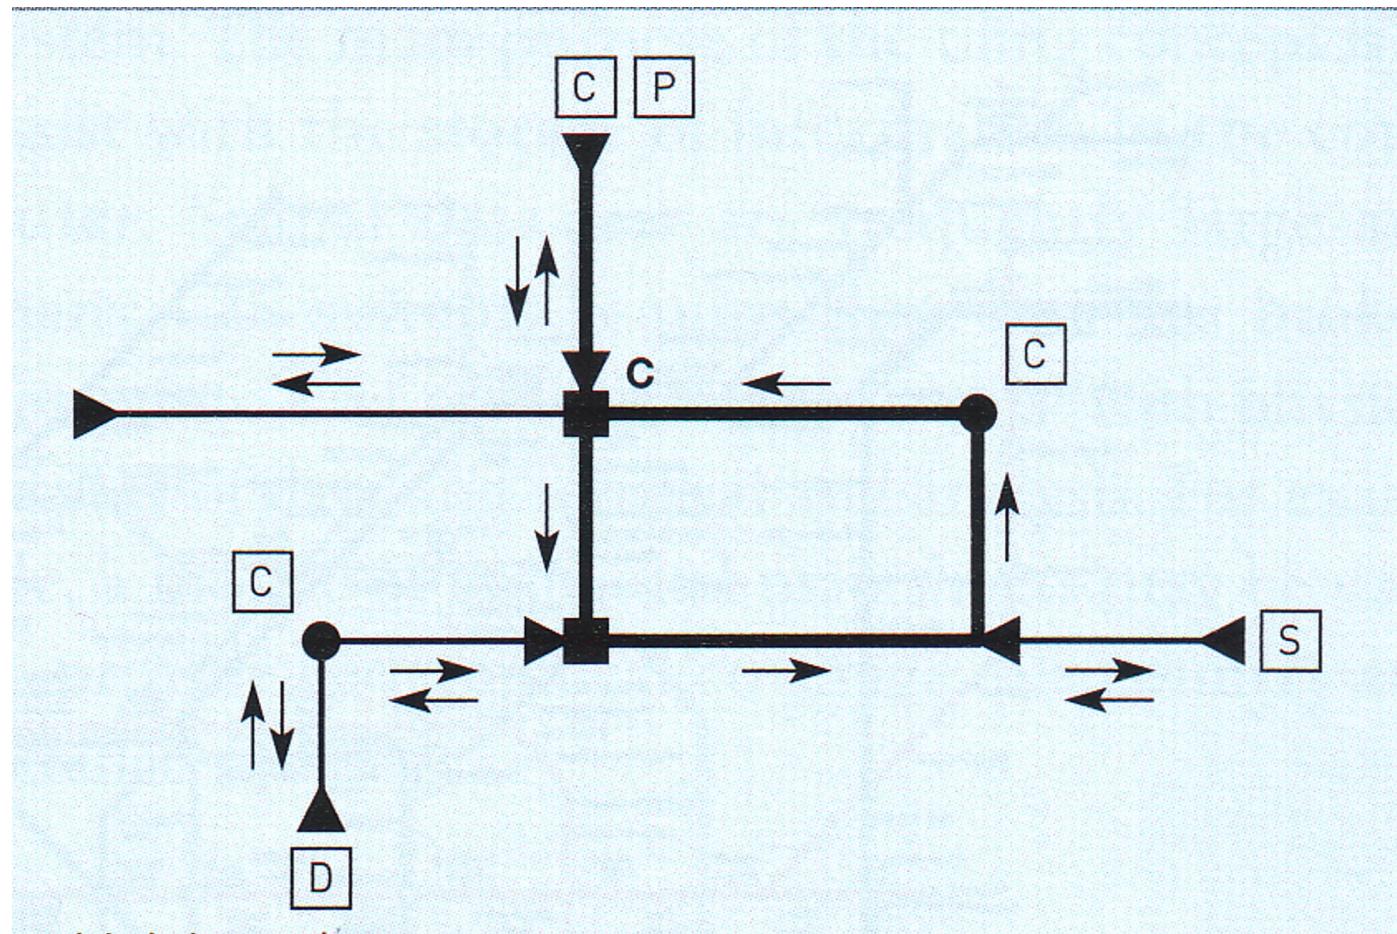

# A River Network

River systems can be represented as a network or a series of networks. Some systems may not connect while other systems may connect naturally or may be connected by canals. The location of locks, river width, river depth, and current can affect the analysis.

# A simple transport network model

## Link impedances:

- One-way flows
- ↔ Two-way flows
- Narrow street – slow traffic flows
- Wide street – faster traffic flows

## Turn impedances:

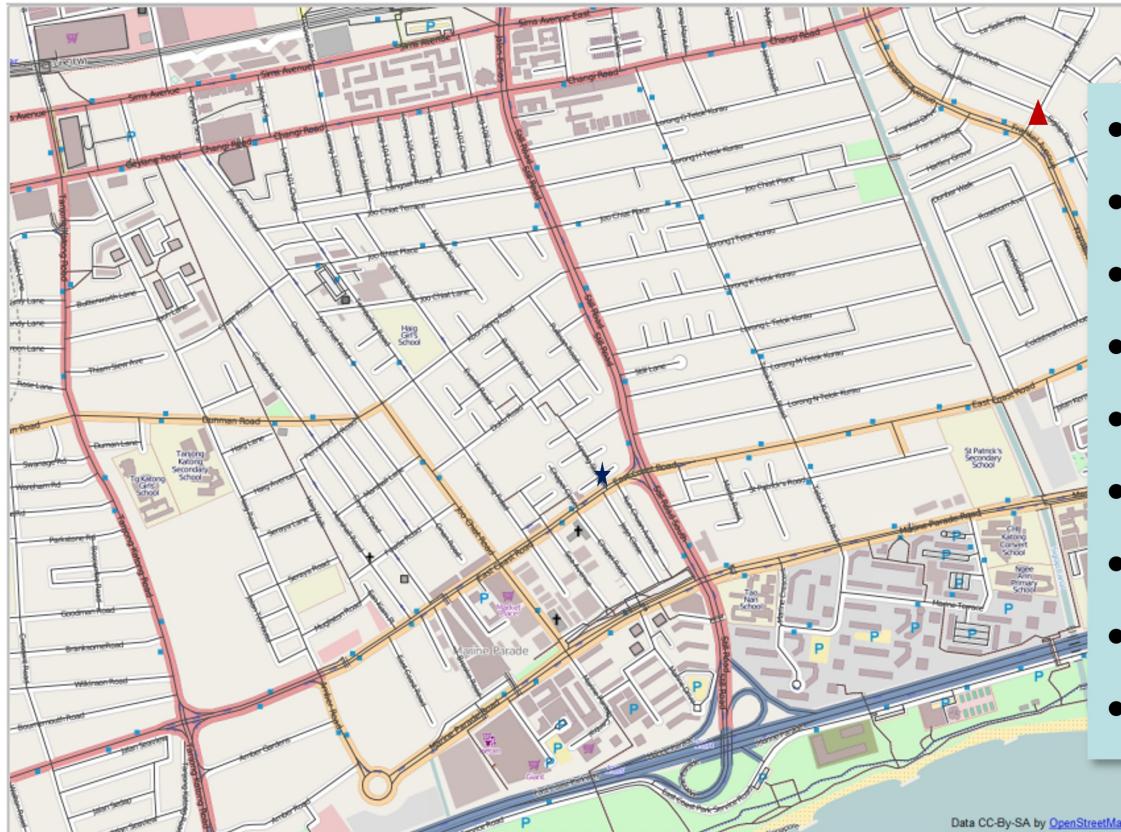

- Junction controlled by traffic lights
- No left turn (turn impedance) in direction of arrow
- c Traffic congestion

## Stops and stop impedances:

- D Van depot (route start and end point)
- S Storage warehouse (point of supply) loading wait time
- C Customer location (point of demand)
- P Parking problems

# Complexity of Urban Network Topology

Beyond nodes and edges, there are more.....

- gid,
- source,
- target,
- cost,
- reverse\_cost,
- x1, y1,
- x2, y2,
- rule,
- to\_cost

# Multilane Expressway

## Multilane Major Road

# Two-way Road

# One-way Road

# Tunnel

## A Tale of Two Roads

## Road facilities slow down traffic

Road sign and traffic light inform about restrictions and rules.

## Road facilities slow down traffic

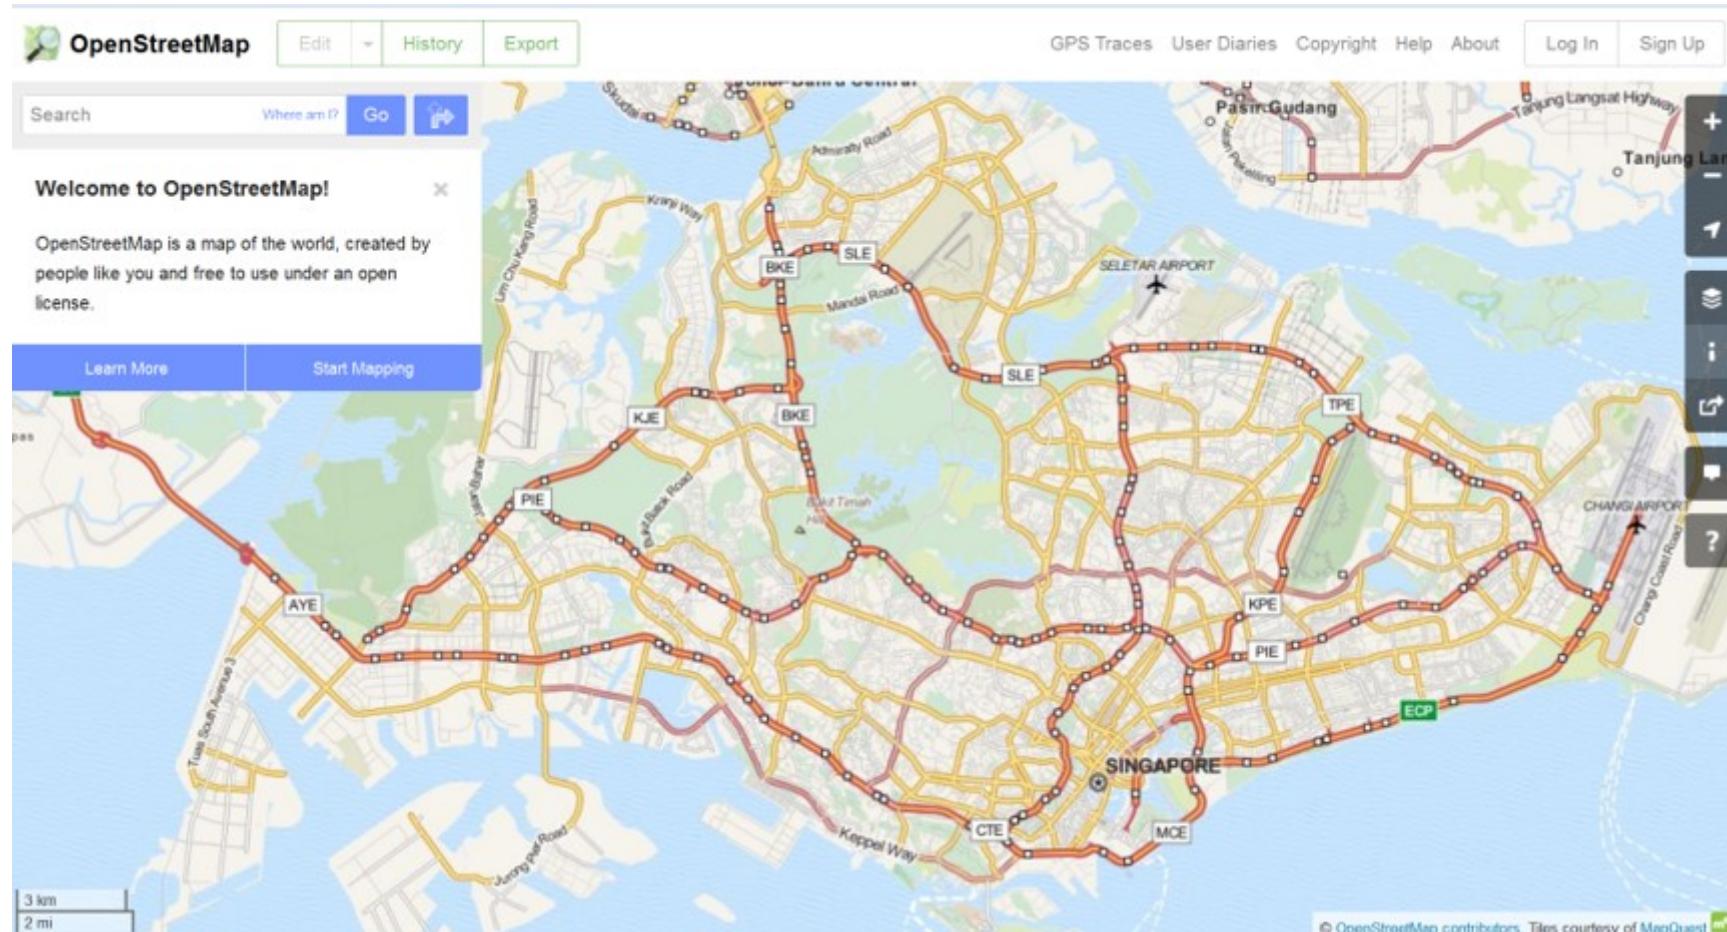

## Road conditions are dynamic

# Poor man network data source

Bulk extract at [Geofabrik](#) free download server.

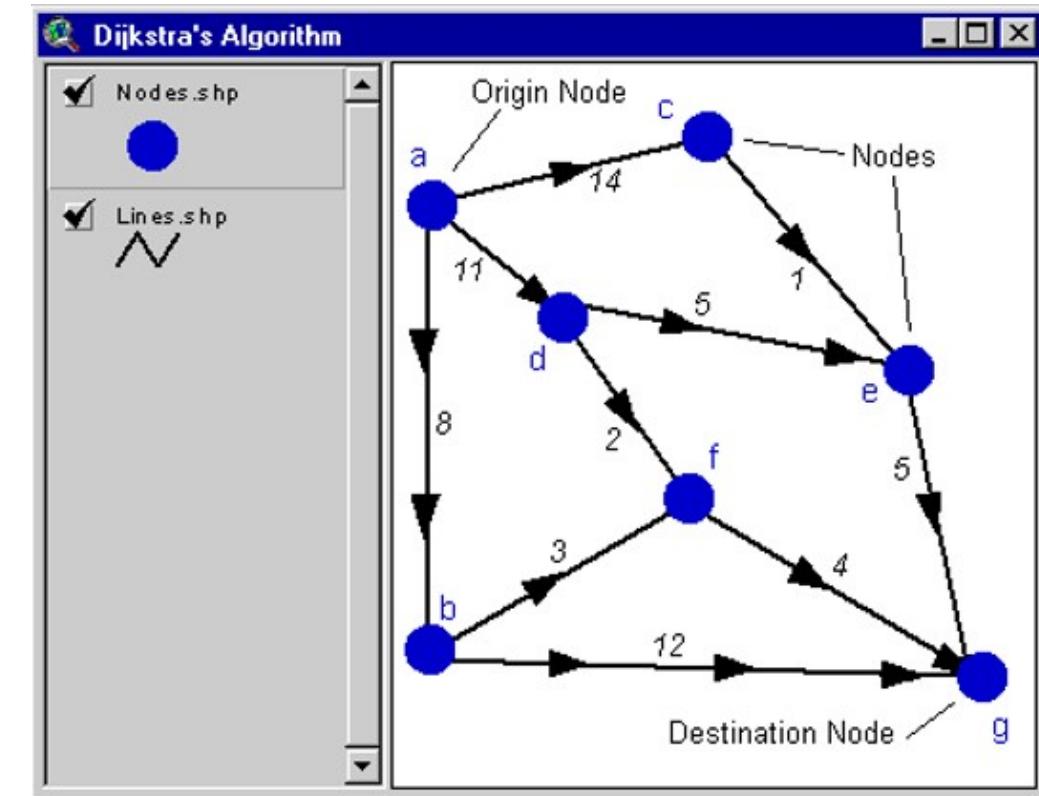

# Shortest Path Analysis

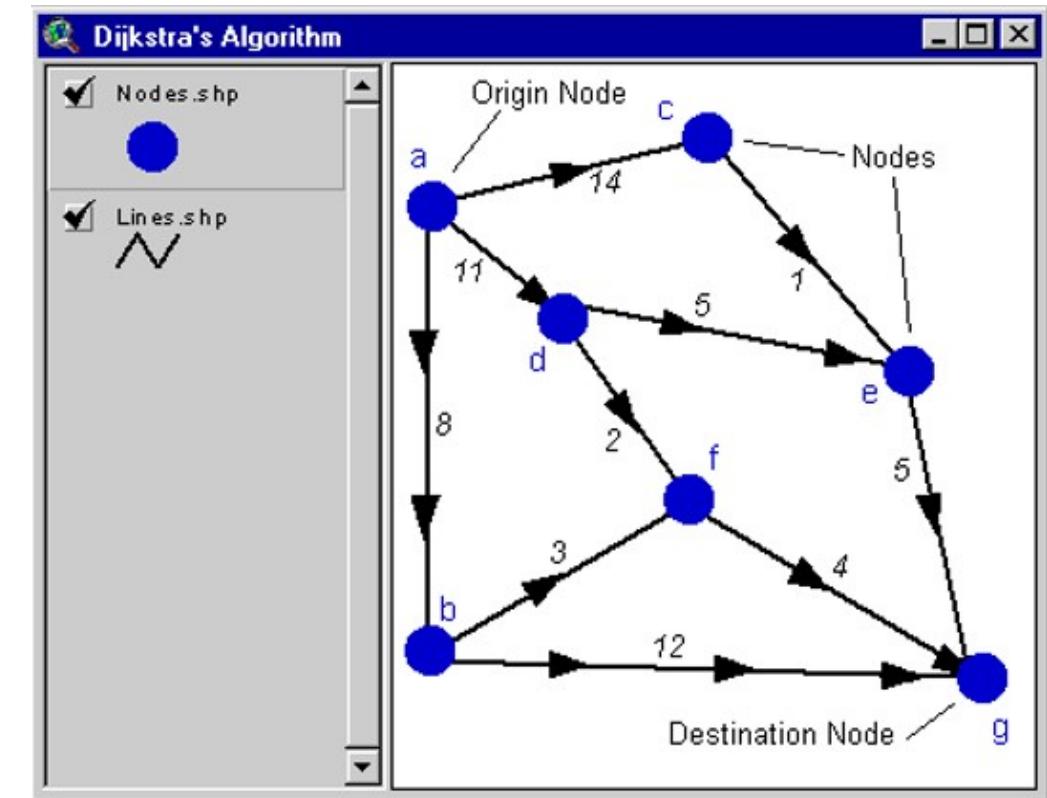

# Dijkstra's Shortest Path Algorithm

- The path that will be calculated depends on which other nodes must be visited and in what order.

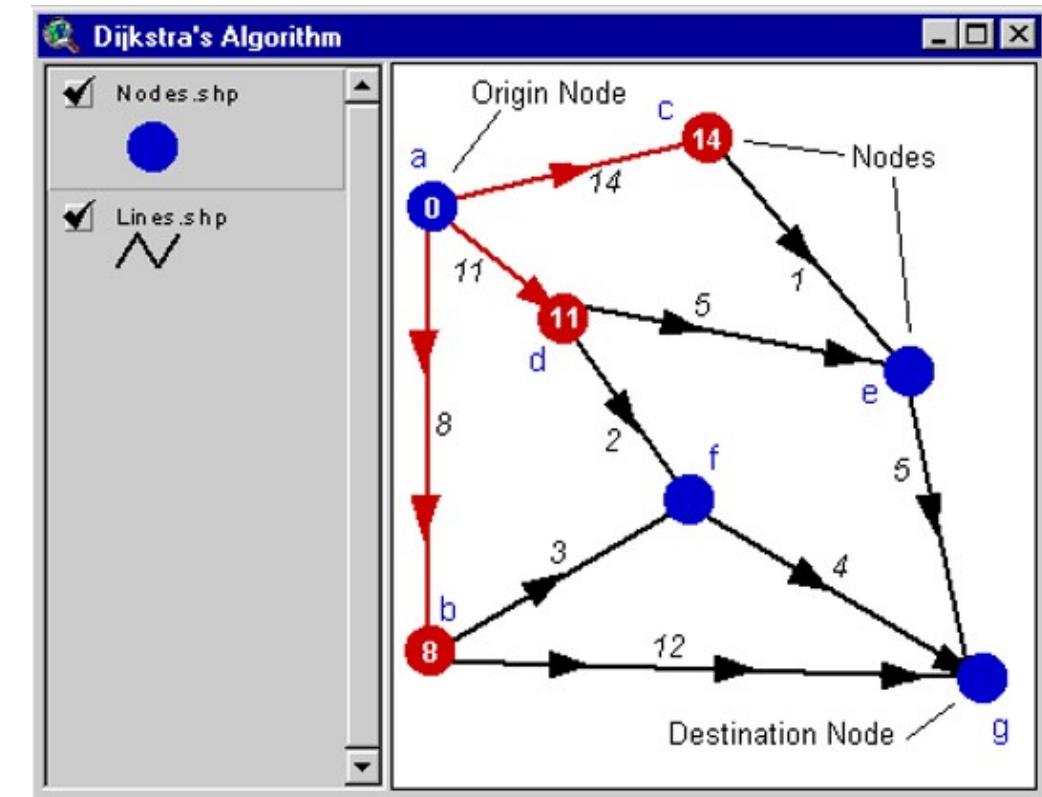

# Dijkstra's Shortest Path Algorithm

- A network consisting of seven nodes and 10 lines.

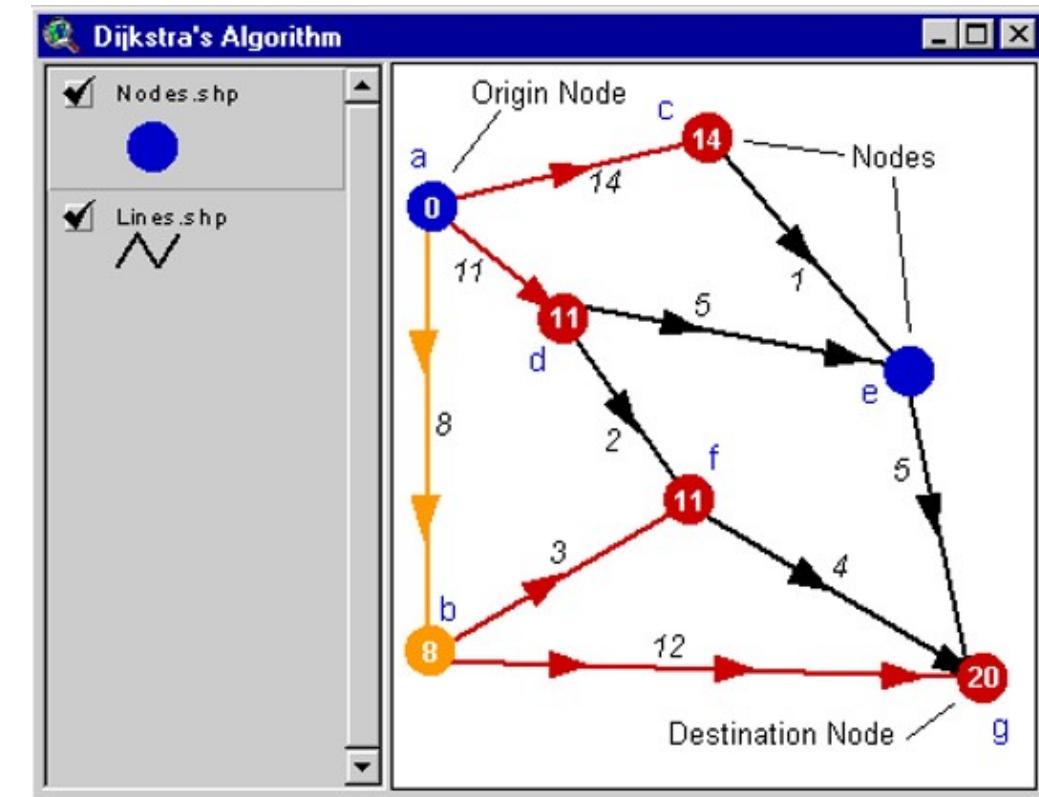

# Dijkstra's Shortest Path Algorithm

- Nodes adjacent to the origin node are in red.

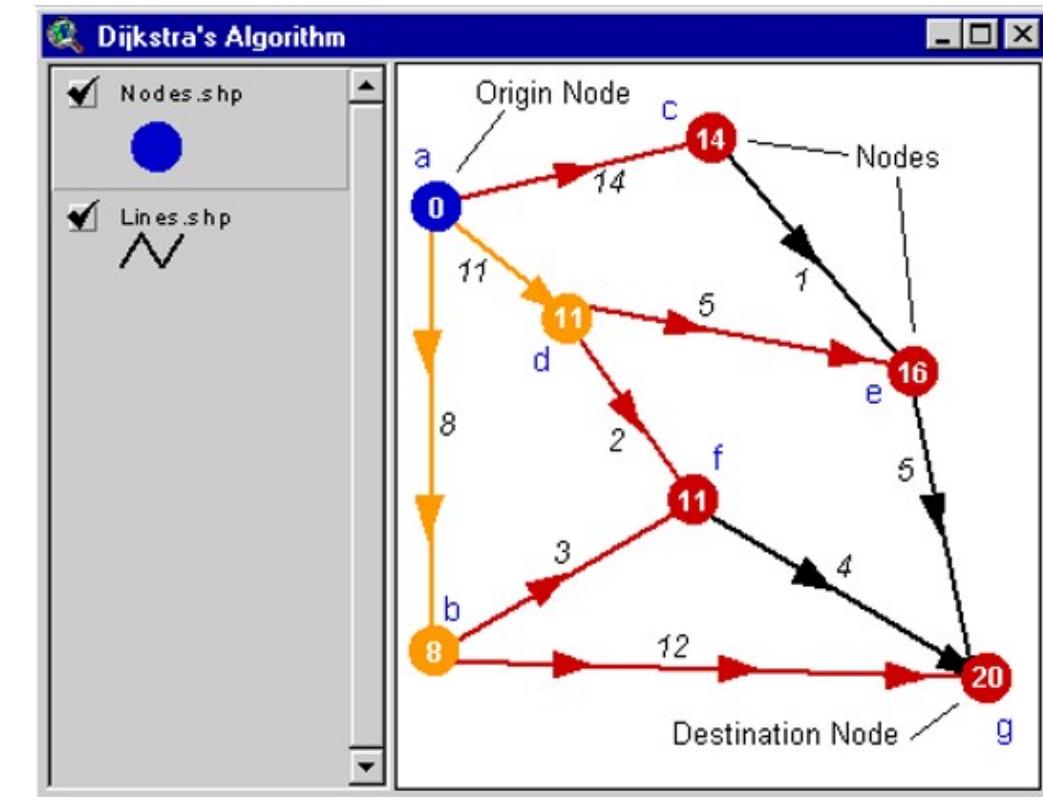

# Dijkstra's Shortest Path Algorithm

- Because the line between nodes a and b has the lowest cost (8), node b becomes a reached node.

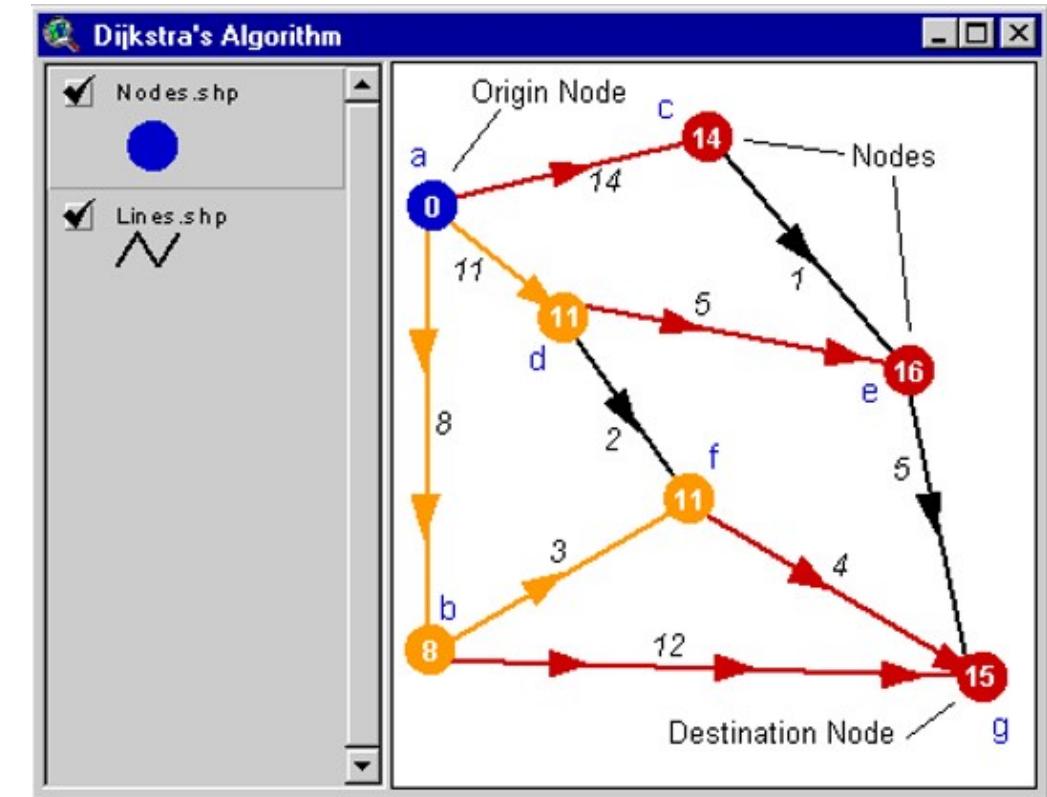

# Dijkstra's Shortest Path Algorithm

- After calculating a reached node, the algorithm continues to scan adjacent nodes.

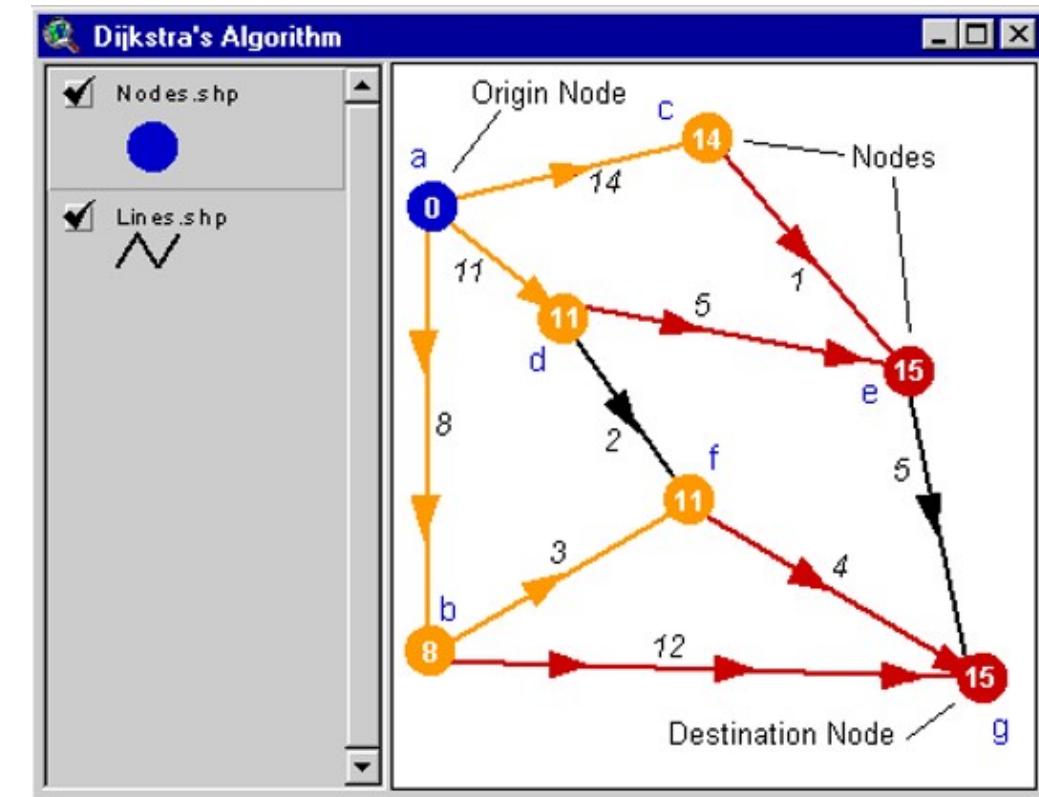

# Dijkstra's Shortest Path Algorithm

- The least cost path now travels from node a to node b to node f.

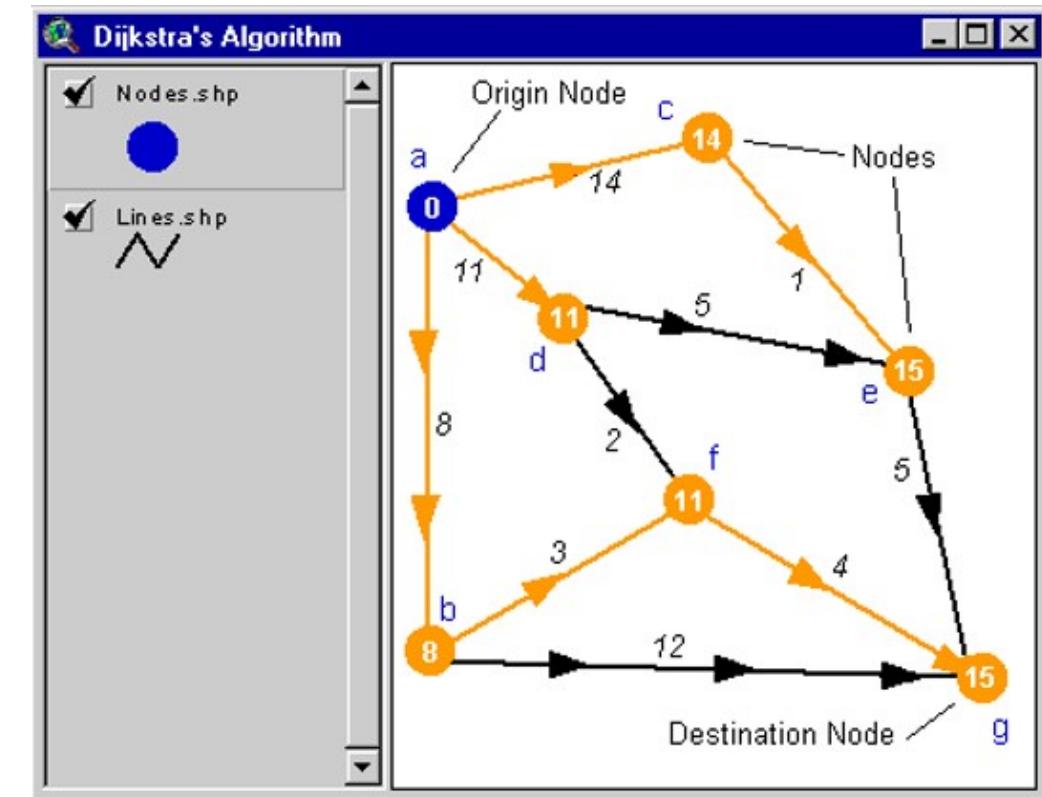

# Dijkstra's Shortest Path Algorithm

- The cost of going from node a to node c to node e is 15, while the cost of going from node a to node d to node e is 16. The algorithm will choose the former, least cost, path.

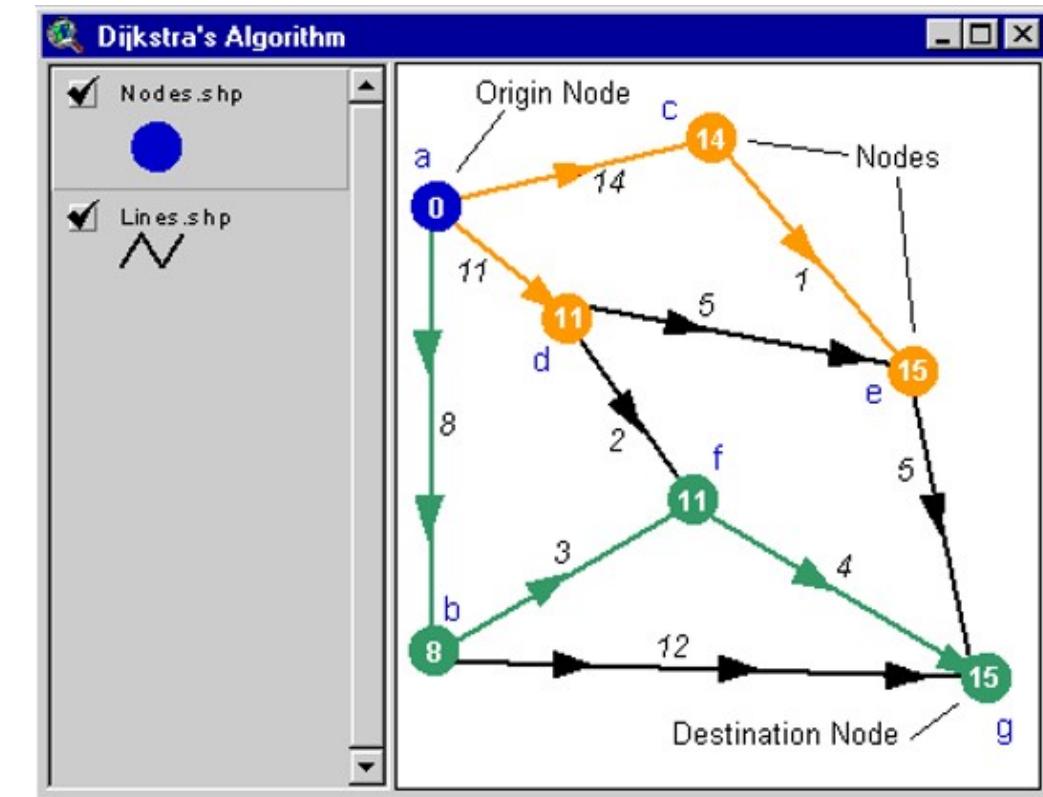

# Dijkstra's Shortest Path Algorithm

- All nodes have now been reached.

# Dijkstra's Shortest Path Algorithm

- The least cost path from node a to node g.

# Fastest Path

- Fastest paths are based on time and you can use any measure of time you choose (seconds, minutes, hours, etc.).

# Travelling salesman problem

- A route can visit many stops in a network. The origin can also be the destination, as the warehouse is in this example delivery route.

# Beyond network model

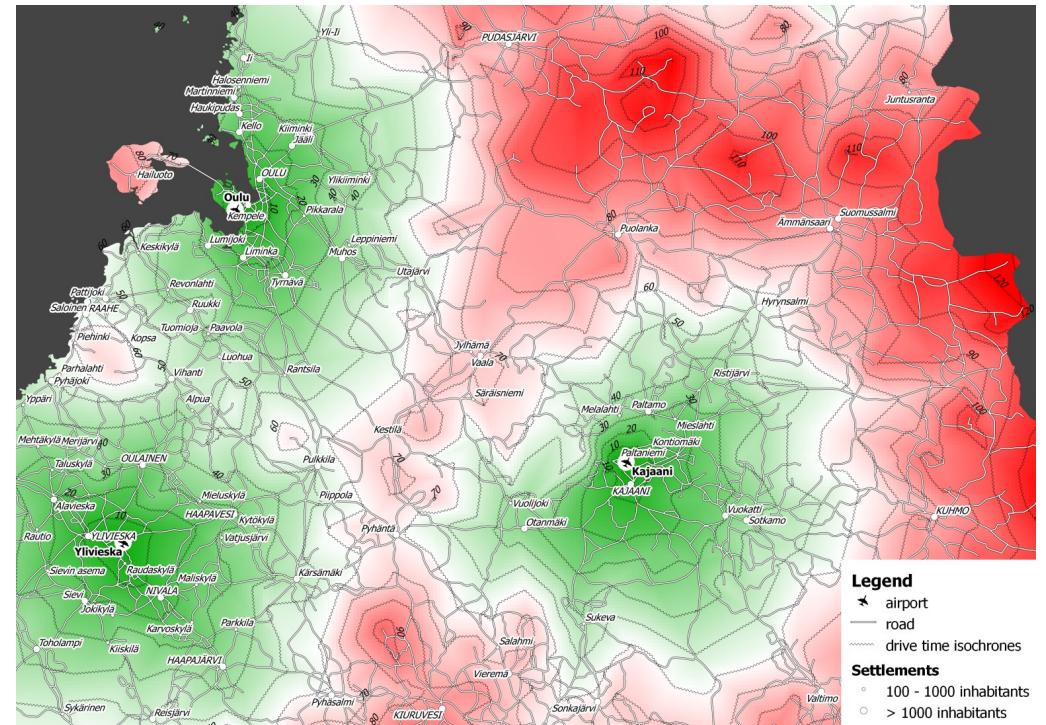

- Accessibility modelling.

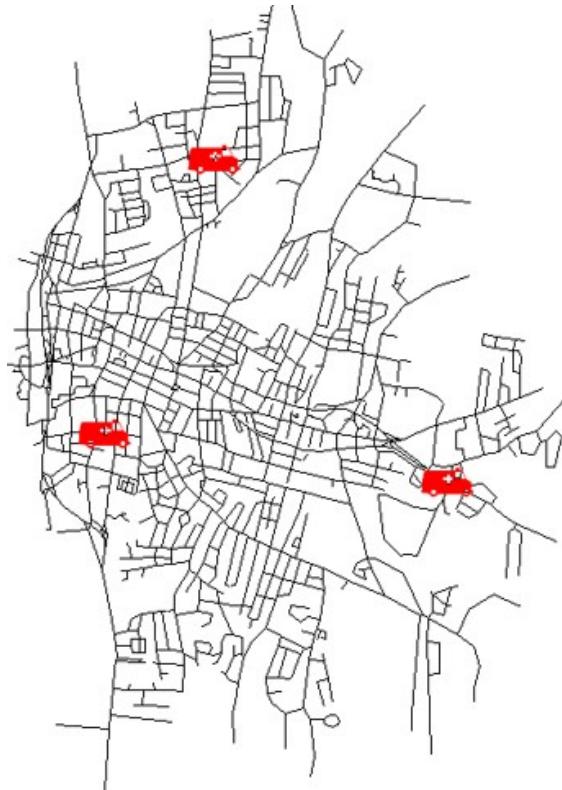

Source: <https://developers.route360.net/index.html>

# Network Drive Time: Accessibility

- If you know what is near a site, you can make better decisions about how suitable the site is for your business needs.

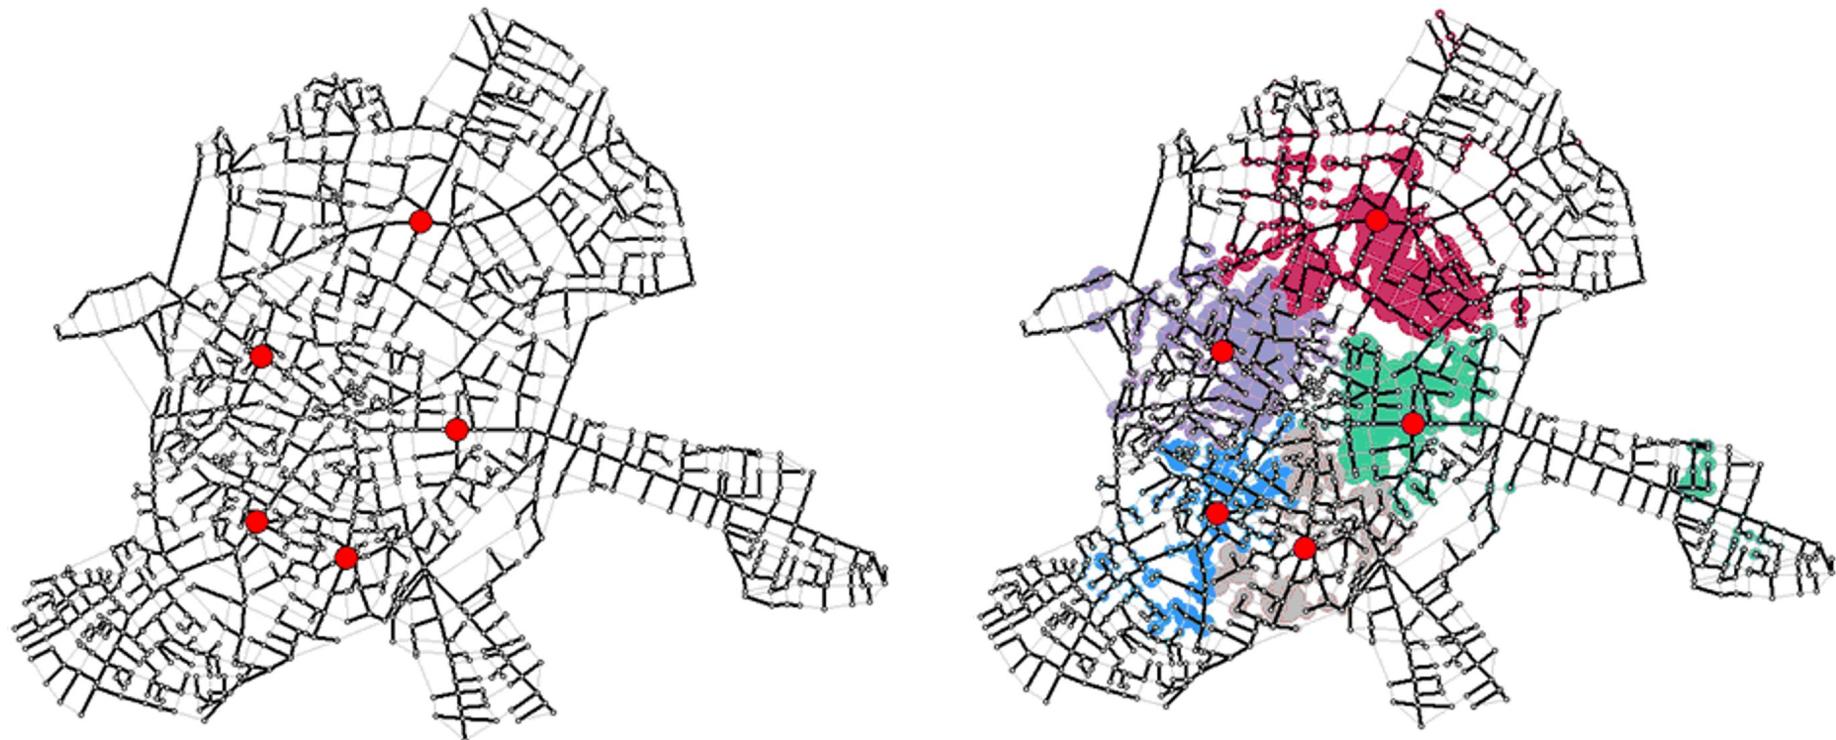

## Network Service Areas

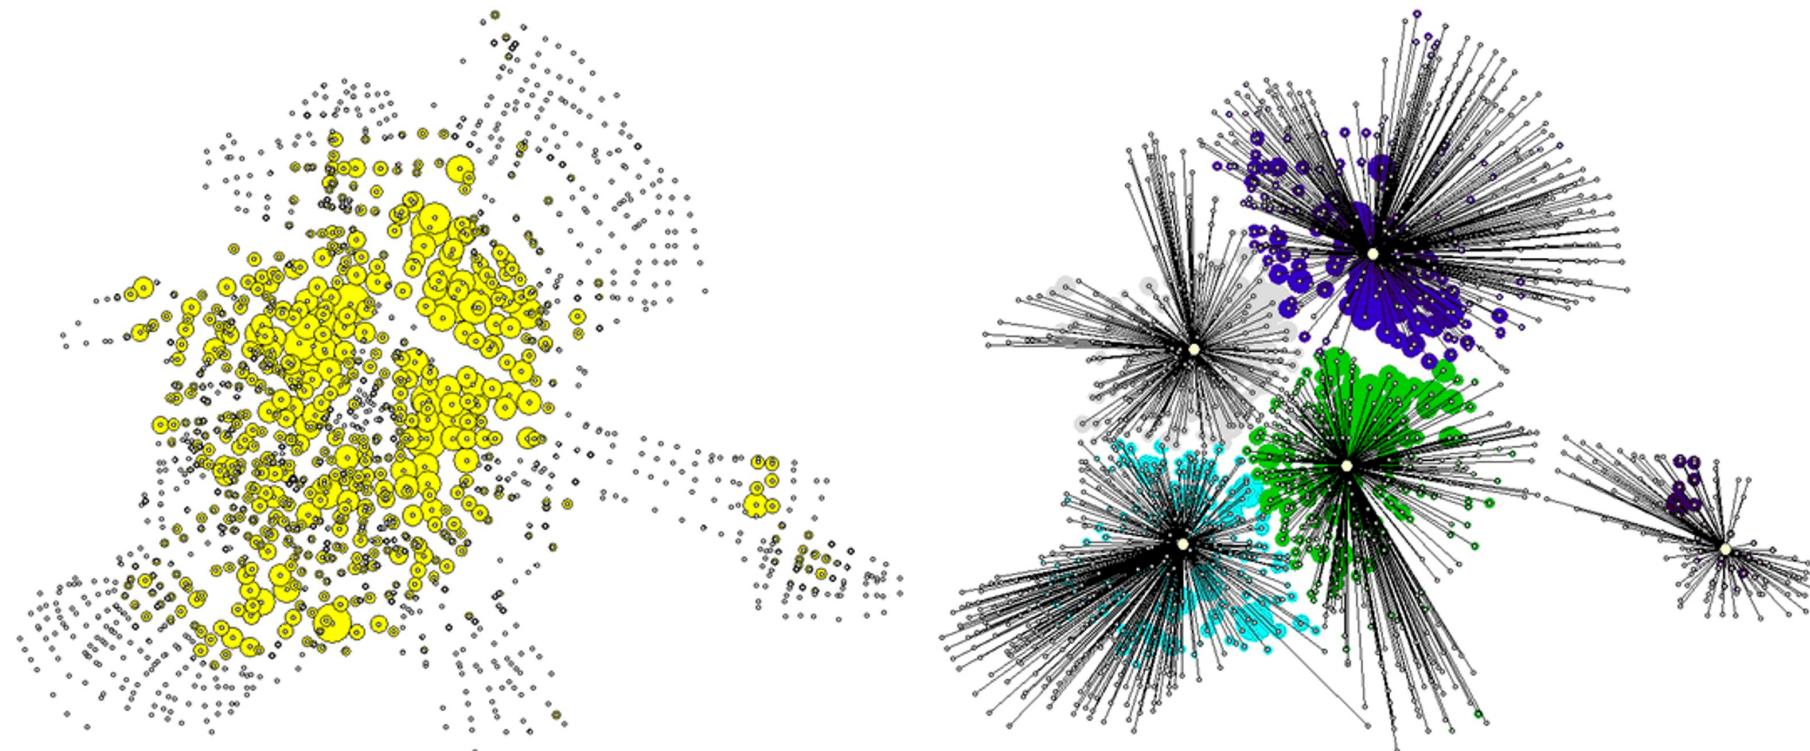

## Facility location – network model

- Given a set of clients, finds the facility location that minimises the path length to travel between the facility to each of the clients.

## Facility location – planar model

- Given a set of clients, finds the facility location that minimises the path length to travel between the facility to each of the clients.

# QGIS Network Analysis Support

- Build in

- ▼  Network analysis

-  Service area (from layer)
-  Service area (from point)
-  Shortest path (layer to point)
-  Shortest path (point to layer)
-  Shortest path (point to point)

- Plug-in

- ▼  QNEAT3 - Qgis Network Analysis Toolbox

- ▼ Distance Matrices

-  OD Matrix from Layers as Lines (m:n)
-  OD Matrix from Layers as Table (m:n)
-  OD Matrix from Points as Table (n:n)
-  OD-Matrix from Points as CSV (n:n)
-  OD-Matrix from Points as Lines (n:n)

- ▼ Iso-Areas

-  Iso-Area as Contours (from Layer)
-  Iso-Area as Contours (from Point)
-  Iso-Area as Interpolation (from Layer)
-  Iso-Area as Interpolation (from Point)
-  Iso-Area as Pointcloud (from Layer)
-  Iso-Area as Pointcloud (from Point)
-  Iso-Area as Polygons (from Layer)
-  Iso-Area as Polygons (from Point)

- ▼ Routing

-  Shortest path (point to point)
